Welcome students to MOOCs series of lectures on advanced probability theory. This is lecture number 26.

(Refer Slide Time: 00:36)

So, if you remember, we are working on convergence of random variables and we have discussed two major types convergence in distribution. When is sequence of random variables  $x_n$  converges to another random variable  $x$  and also convergence in probability denote that as a sequence of random variable  $x_n$  converging to another random variable  $x$ .

We have stated that convergence in probability is a stronger statement then convergence in distribution, why because there may be situation when a sequence of random variables  $x_n$  converges in distribution  $x$  but not in probability. On the other hand, if  $x_n$  convergence in probability to  $x$  then  $x_n$  also converges in distribution to  $x$ .

(Refer Slide Time: 03:56)

The image shows a screenshot of a Windows Journal window titled "Note1 - Windows Journal". The window contains handwritten text and mathematical expressions in purple ink. The text reads: "Thm: If  $X_n \xrightarrow{p} X$  then  $X_n \xrightarrow{L} X$ ." followed by "Pf: Consider the event  $X_n \leq x$ . We can write it as:  $(X_n \leq x) = ((X_n \leq x) \cap (x \geq x + \epsilon)) \cup ((X_n \leq x) \cap (x < x + \epsilon))$  where  $\epsilon > 0$ ." followed by "Note that the above event is contained in the following:  $\subseteq (x < x + \epsilon) \cup ((X_n \leq x) \cap (x \geq x + \epsilon))$ ". The window has a standard Windows interface with a menu bar (File, Edit, View, Insert, Actions, Tools, Help) and a toolbar with various drawing tools. The taskbar at the bottom shows the Start button, several application icons, and the system clock displaying 11:41 AM on 06-Mar-20.

Thm: If  $X_n \xrightarrow{p} X$  then  $X_n \xrightarrow{L} X$ .

Pf: Consider the event  $X_n \leq x$ .  
We can write it as:

$$(X_n \leq x) = ((X_n \leq x) \cap (x \geq x + \epsilon)) \cup ((X_n \leq x) \cap (x < x + \epsilon))$$

where  $\epsilon > 0$ .

Note that the above event is contained in the following:

$$\subseteq (x < x + \epsilon) \cup ((X_n \leq x) \cap (x \geq x + \epsilon))$$

So, let us prove the result. So, theorem if  $x_n$  converges in p in probability to  $x$  then  $x_n$  converges in distribution to  $x$  proof. Consider the event  $x_n$  less than or equal to  $x$ . Now, we can write it as  $x_n$  less than equal to  $x$  is equal to union of two disjoint events  $x_n$  less than equal to  $x$  and  $x$  is greater than equal to  $x$  plus epsilon union  $x_n$  less than equal to  $x$  and  $x$  less than  $x$  plus epsilon where epsilon greater than zero that is it is a small quantity.

Note that the above event is contained the following that is, this is contained in  $x$  less than  $x$  plus epsilon union  $x_n$  less than equal to  $x$  and  $x$  greater than equal to  $x$  plus epsilon. Why? Because I am keeping the same event here these two are same, but this is a super event of this one as we have deleted this condition.

(Refer Slide Time: 06:29)

The image shows a handwritten derivation in a Windows Journal window. The text is as follows:

$$\therefore P(X_n \leq x) \leq P(X \leq x + \epsilon) + P((X_n \leq x) \cap (X \geq x + \epsilon))$$

$\therefore$  If  $F_n$  denotes the cdf of  $X_n$ , then

$$F_n(x) \leq F(x + \epsilon) + \underbrace{P((X_n \leq x) \cap (X \geq x + \epsilon))}_{\text{where } F \text{ is the cdf of } X}$$

$$\leq F(x + \epsilon) + P(|X_n - X| \geq \epsilon)$$

$\therefore \left. \begin{matrix} X_n \leq x \\ \& X \geq x + \epsilon \end{matrix} \right\} \Rightarrow \text{the distance between } X_n \& X \text{ is at least } \epsilon.$

Therefore, probability  $x_n$  less than equal to  $x$  is less than equal to probability  $x$  less than equal to small  $x$  plus epsilon plus probability  $x_n$  less than equal to  $x$  intersected with  $x$  greater than equal to  $x$  plus epsilon. Therefore, if  $f_n$  denote the cumulative distribution function of  $x_n$  then we can write  $f_n(x)$  is less than equal to  $f$  at  $x$  plus epsilon plus probability  $x_n$  less than equal to  $x$  intersected with  $x$  greater than equal to  $x$  plus epsilon, where  $f$  is the cumulative distribution function of  $x$ .

Now, this is less than equal to  $f(x)$  plus epsilon plus probability modulus of  $x_n$  minus  $x$  is greater than equal to epsilon. How, since, from this event, we can see that  $x_n$  is less than equal to  $x$  and  $x$  is capital  $X$  is greater than equal to  $x$  plus epsilon they were together they imply that the distance between  $x_n$  and  $x$  is at least epsilon.

And since, this can happen in some other ways also, therefore, this event is contained in this event and therefore, this probabilities are bigger than this probability.

(Refer Slide Time: 09:05)

In a similar way:

$$F(x-\epsilon) = P(X \leq x-\epsilon)$$

$$= P(\underbrace{((X \leq x-\epsilon) \cap (X_n > x))}_{((X \leq x-\epsilon) \cap (X_n \leq x))} \cup \underbrace{((X \leq x-\epsilon) \cap (X_n \leq x))}_{(X_n \leq x)})$$

$$\leq P(|X_n - X| \geq \epsilon) + F_n(x)$$

$$\therefore F(x-\epsilon) - P(|X_n - X| \geq \epsilon) \leq F_n(x)$$

Also, we have found:

$$F_n(x) \leq F(x+\epsilon) + P(|X_n - X| \geq \epsilon)$$
  

$$\therefore P(X_n \leq x) \leq P(X \leq x+\epsilon) + P((X_n \leq x) \cap (X \geq x+\epsilon))$$

$\therefore$  If  $F_n$  denotes the cdf of  $X_n$ , then

$$F_n(x) \leq F(x+\epsilon) + \underbrace{P((X_n \leq x) \cap (X \geq x+\epsilon))}_{\text{where } F \text{ is the cdf of } X}$$

$$\leq F(x+\epsilon) + P(|X_n - X| \geq \epsilon) \checkmark$$

$\therefore \left. \begin{matrix} X_n \leq x \\ \& X \geq x+\epsilon \end{matrix} \right\} \Rightarrow$  the distance between  $X_n$  &  $X$  is at least  $\epsilon$ .

In a similar way,  $f$  at small  $x$  minus epsilon is equal to probability  $x$  less than equal to  $x$  minus epsilon is equal to probability  $x$  less than equal to small  $x$  minus epsilon. And  $x_n$  is greater than  $x$  union with  $x$  less than equal to small  $x$  minus epsilon intersected with  $x_n$  less than equal to  $x$ . So, again I have divided this event as a union of two different disjoint events less than equal to probability modulus of  $x_n$  minus  $x$  greater than equal to epsilon.

Again by a similar logic  $x_n$  is greater than  $x$ , but  $x$  is smaller than  $x$  minus epsilon. Therefore, the distance between them is greater than equal to epsilon plus this whole event is contained in  $x_n$  less than equal to  $x$ . Therefore, we are writing their  $f_n(x)$  therefore,  $f$  at  $x$  minus epsilon minus

probability modulus of  $x_n$  minus  $x$  greater than equal to  $\epsilon$  is less than equal to a  $f_{n,x}$  also we have found if we go back.

We have found that  $f_{n,x}$  is less than equal to this entire quantity, therefore we can write it is that  $f_{n,x}$  is less than equal to  $f$  at  $x$  plus  $\epsilon$  plus probability modulus of  $x_n$  minus  $x$  greater than equal to  $\epsilon$  greater than equal to  $\epsilon$ .

(Refer Slide Time: 11:50)

$\therefore$  Together we write:  

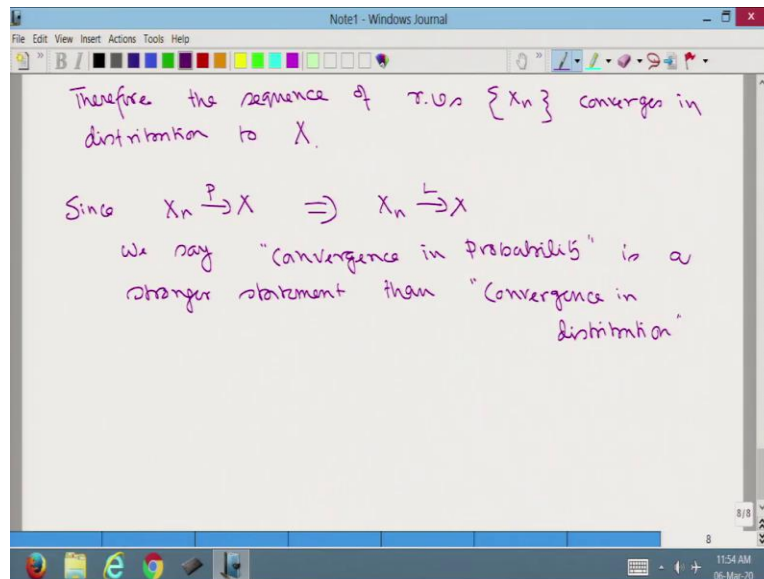

$$F(x-\epsilon) - \underbrace{P(|X_n - x| \geq \epsilon)}_{\rightarrow 0} \leq F_n(x) \leq F(x+\epsilon) + \underbrace{P_n(|X_n - x| \geq \epsilon)}_{\rightarrow 0}$$
 Now it is given that  $X_n \xrightarrow{P} x$ .  
 This implies  $P(|X_n - x| \geq \epsilon) \rightarrow 0$  as  $n \rightarrow \infty$   
 Therefore for sufficiently large  $n$   

$$F(x-\epsilon) \leq F_n(x) \leq F(x+\epsilon)$$
 This is true for any  $\epsilon > 0$  however small it is.  
 Since  $x$  is a point of continuity for  $F(x)$ , we  
 can say that  $F_n(x) \rightarrow F(x)$ .

So, together we write  $f$  at  $x$  minus  $\epsilon$  minus probability modulus of  $x_n$  minus  $x$  greater than equal to  $\epsilon$  less than equal to  $f$  and  $x$  less than equal to  $f$  at  $x$  plus  $\epsilon$  plus probability modulus of  $x_n$  minus  $x$  greater than  $\epsilon$ . Now, it is given that  $X_n$  converges in probability to  $x$ , this implies probability modulus of  $x_n$  minus  $x$  greater than equal to  $\epsilon$  converges to 0 as  $n$  goes to infinity.

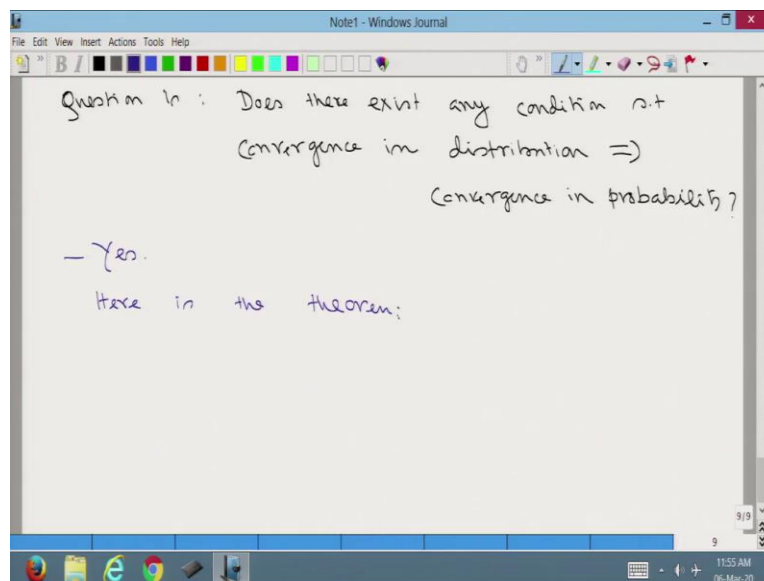

That is therefore, for sufficiently large  $n$  we can say that  $f$  at  $x$  minus  $\epsilon$  less than equal to  $f_n$   $x$  less than equal to  $f_x$  plus  $\epsilon$ , why, because this term is going to 0. And similarly, this term is also going to 0. This is true for any  $\epsilon$  greater than 0. However, small it is since  $x$  is a point of continuity for  $f_x$  we can say that  $f_{n,x}$  converges to  $f_x$ .

(Refer Slide Time: 14:30)

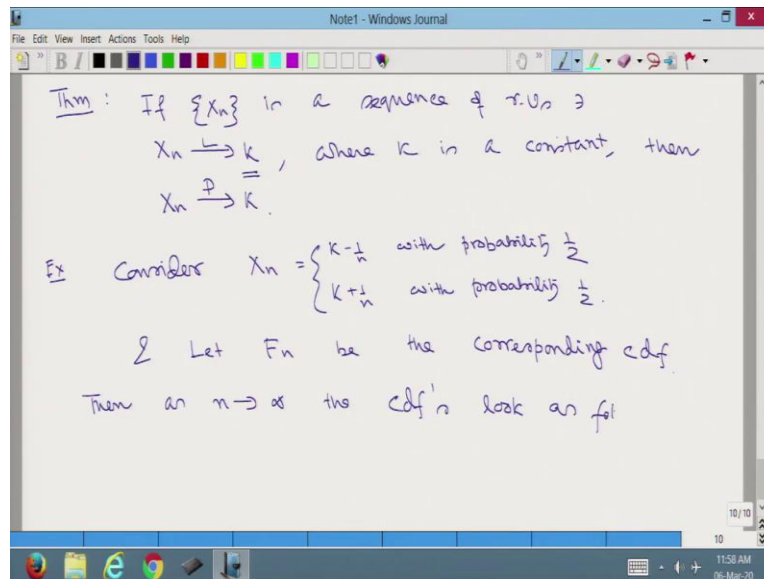

Therefore, the sequence of random variables  $x_n$  converges in distribution to  $x$ . Therefore, since convergence in  $P$  in probability implies convergence in distribution. We say convergence in probability is a stronger statement then convergence in distribution.

(Refer Slide Time: 15:50)

Question is does there exist any condition such that convergence in distribution implies convergence in probability, the answer is yes and here is the theorem.

(Refer Slide Time: 16:50)

If  $x_n$  is a sequence of random variables such that  $x_n$  converges in distribution to a constant  $K$  then  $x_n$  converges in probability to  $K$  that is, here we are looking at a degenerate case  $x_n$  is a distribution, which is converging to a constant  $K$  in distribution, then  $x_n$  converges in probability to  $K$  as well.

So, let me first give you an example, Suppose, consider  $x_n$  to be distributed as follows, it takes the value  $k$  minus  $1/n$  with probability half and  $k$  plus  $1/n$  with probability half therefore, and let  $f_n$  be the corresponding cumulative distribution function. Then as  $n$  goes to infinity, the cdf's look as follows.

(Refer Slide Time: 19:01)

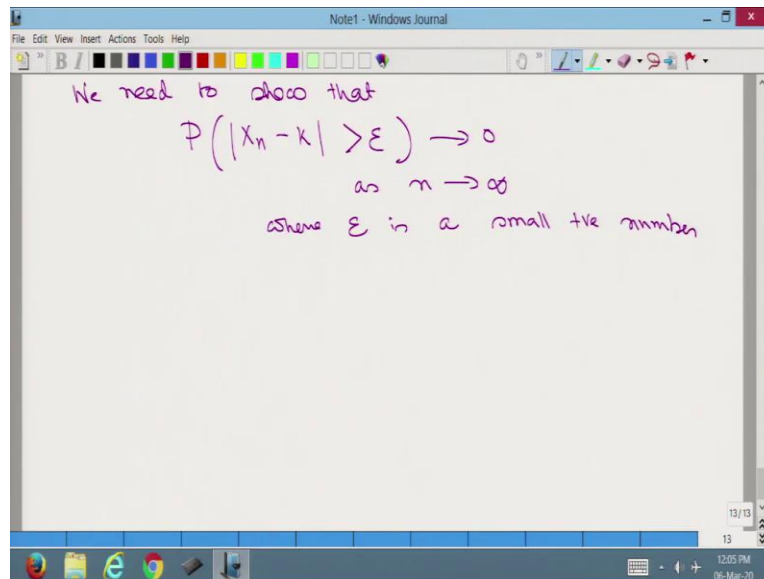

Therefore, it is cdf's look as follows. Suppose this is  $k$ , this is  $k$  minus 1 and this is  $k$  plus 1. Therefore,  $x_1$  will have a cdf which is 0 till  $k$  minus 1 at  $k$  minus 1 it jumps to half and then it continues till  $k$  plus 1 with half then it jumps to 1 at  $k$  plus half and continues like that. So, that is the cdf of  $x_1$ ,  $x_2$  will take the values  $k$  minus half and  $K$  plus half with probabilities half and half.

Therefore, each Cdf will be 0 till  $k$  minus half it is going to be half at  $k$  minus half and it is going to be 1 at  $k$  plus half. Therefore, this is the shape of  $f_2$  therefore what is going to be the Cdf of say  $k$  minus 1 upon  $n$  when  $n$  is large. So, let us call this value  $k$  minus 1 upon  $n$  and this value to be  $k$  plus 1 upon  $a$  then each cdf will look like this it is how 0 till  $k$  minus 1 upon  $n$  in half at  $k$  plus half at  $k$  minus 1 upon  $n$  it will continue like this till the point  $k$  plus 1 upon  $n$  then it will make a jump to 1 and continue at 1 throughout.

Therefore, what is happening we can understand that as  $n$  increases, we are getting smaller and smaller intervals around  $k$  where the actual jump is occurring. Therefore, this by taking  $n$  to be very large we come to the intervals  $k$  minus epsilon to  $k$  plus epsilon. If this is clear, then let us proceed as follows.

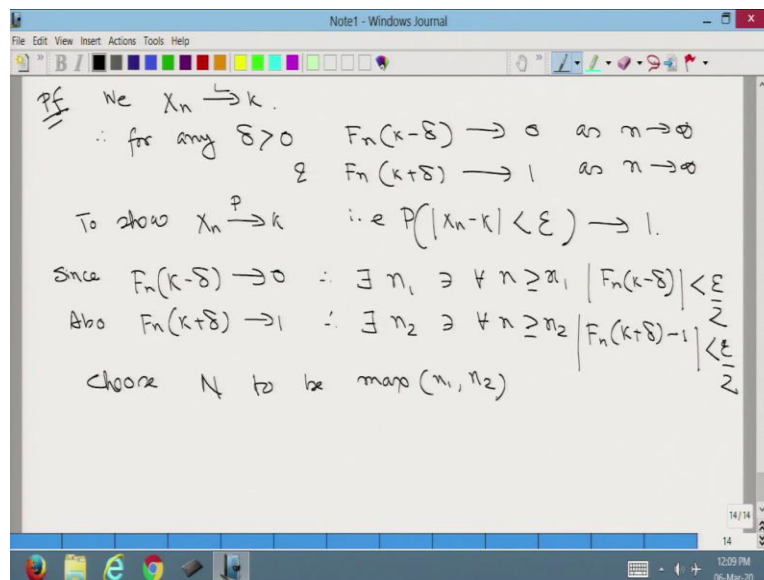

(Refer Slide Time: 22:24)

We need to show that probability modulus of  $x_n$  minus  $k$  greater than  $\epsilon$  goes to zero as  $n$  goes to infinity where  $\epsilon$  is a small positive number.

(Refer Slide Time: 23:01)

So, proof we have  $x_n$  converges in distribution to  $k$  therefore, for any  $\delta$  greater than 0  $F_n(k - \delta)$  goes to 0 as  $n$  goes to infinity and  $F_n(k + \delta)$  goes to 1 as  $n$  goes to infinity to show  $X_n$  converges in probability to  $k$  that is probability modulus of  $X_n$  minus  $k$  less than  $\epsilon$  goes to one since  $F_n(k - \delta)$  converges to 0, therefore, there exist  $n_1$  such that for

all  $n$  greater than equal to  $n_1$  modulus of  $F_n(k) - 1$  is less than  $\epsilon/2$  also  $F_n(k) + \delta$  goes to 1. Therefore, there exist  $n_2$  such that for all  $n$  greater than equal to  $n_2$  modulus of  $F_n(k) + \delta - 1$  is less than  $\epsilon/2$  choose  $n$  to be maximum of  $n_1$  and  $n_2$ .

(Refer Slide Time: 25:08)

$\therefore$  For all  $n \geq N$  let us put bound on  $F_n(k+\delta) - F_n(k-\delta)$ .  
 $\therefore |F_n(k-\delta)| \leq \frac{\epsilon}{2} \therefore -\frac{\epsilon}{2} \leq -F_n(k-\delta) \leq \frac{\epsilon}{2}$   
 Also  $|F_n(k+\delta) - 1| \leq \frac{\epsilon}{2} \therefore 1 - \frac{\epsilon}{2} \leq F_n(k+\delta) \leq 1 + \frac{\epsilon}{2}$   
 $\therefore$  By adding:  $\forall n \geq N$   
 $1 - \epsilon \leq F_n(k+\delta) - F_n(k-\delta) \leq 1 + \epsilon$   
 Since this is true for any arbitrary  $\delta$ , however small it is we conclude that  $F_n \xrightarrow{P} F$  which is the cdf of Variable  $X : k$  with probability 1.

Therefore, for all  $n$  greater than equal to  $n$ , let us put bound on  $F_n(k) + \delta - F_n(k) - \delta$  since, modulus of  $F_n(k) - 1$  less than equal to  $\epsilon/2$  therefore,  $1 - \epsilon/2 \leq F_n(k) \leq 1 + \epsilon/2$  also modulus of  $F_n(k) + \delta - 1$  less than equal to  $\epsilon/2$ .

Therefore,  $1 - \epsilon/2 \leq F_n(k) + \delta \leq 1 + \epsilon/2$ . Therefore, by adding for all  $n$  greater than equal to  $n_1$   $1 - \epsilon/2 \leq F_n(k) + \delta - F_n(k) - \delta \leq 1 + \epsilon/2$ . Since this is true for any arbitrary  $\delta$  however small it is, we conclude that  $F_n$  converges in probability to  $F$  which is the cdf of variable  $X$  defined as it takes the value  $k$  with probability 1.

(Refer Slide Time: 28:11)

Ex Let  $X_1, X_2, \dots$  be independent r.v.s s.t. each  $X_i \sim U[-1, 1]$ .  
Consider the sequence of r.v.s  $Y_1, Y_2, Y_3, \dots$   
s.t.  $Y_i = \max(X_1, X_2, \dots, X_i) \quad \forall i = 1, 2, 3, \dots$   
show that  $Y_n \xrightarrow{P} 1$ .

So, that proves that result let me now give you an example of convergence in probability let  $x_1, x_2, x_n$  be independent random variables such that each  $x_i$  is distributed as uniform minus 1 comma 1. Consider the sequence of random variables  $Y_1, Y_2, Y_3$  like that such that  $Y_i$  is equal to maximum of  $X_1, X_2, X_i$  for all  $i$  is equal to 1, 2, 3 up to infinity. Show that  $Y_n$  converges in probability to 1.

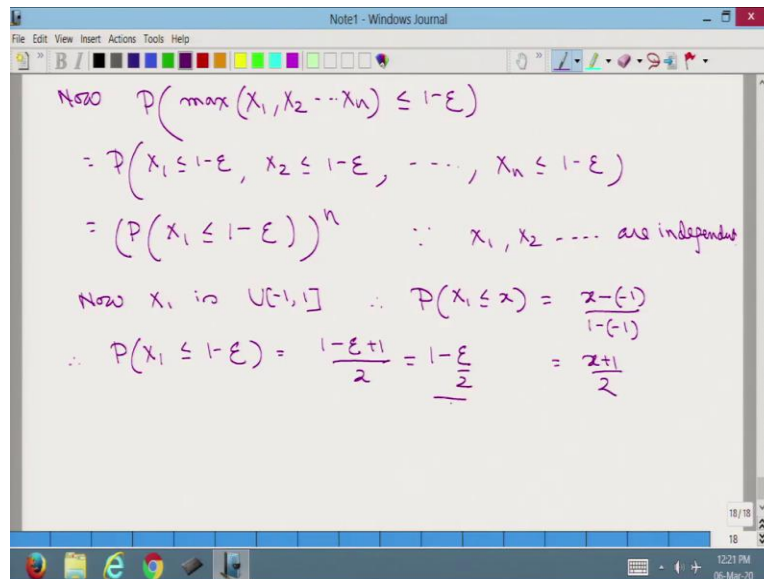

(Refer Slide Time: 29:32)

Sol<sup>n</sup> Let  $\epsilon > 0$   
Then  $P(|Y_n - 1| \geq \epsilon)$   
 $= P(Y_n \geq 1 + \epsilon) + P(Y_n \leq 1 - \epsilon)$   
 $= P(\max(X_1, X_2, \dots, X_n) \geq 1 + \epsilon) + P(\max(X_1, X_2, \dots, X_n) \leq 1 - \epsilon)$   
 $\because X_i$ 's are  $U[-1, 1] \quad \therefore P(\max(X_1, X_2, \dots) \geq 1 + \epsilon) = 0$   
 $\therefore P(|Y_n - 1| \geq \epsilon) = P(\max(X_1, \dots, X_n) \leq 1 - \epsilon)$

Solution let  $\epsilon$  be greater than 0 then probability modulus of  $y_n - 1$  greater than equal to  $\epsilon$  is equal to probability  $y_n$  greater than equal to  $1 + \epsilon$  plus probability  $y_n$  less than equal to  $1 - \epsilon$  is equal to probability maximum of  $X_1, X_2, X_n$  greater than equal to  $1 + \epsilon$  plus probability maximum of  $X_1, X_2, X_n$  is less than equal to  $1 - \epsilon$ .

Since  $x_i$  are uniform over,  $-1$  to  $1$ , therefore probability maximum of  $x_1, x_2$  etc greater than equal to  $1 + \epsilon$  is equal to 0, because the upper limit of the value that the random variables can take is only 1. Therefore, probability modulus of  $y_n - 1$  greater than equal to  $\epsilon$  boils down to probability maximum of  $X_1, X_2, X_n$  is less than equal to  $1 - \epsilon$ .

(Refer Slide Time: 31:49)

The image shows a screenshot of a Windows Journal window titled "Note1 - Windows Journal". The window contains handwritten mathematical derivations in purple ink. The derivations are as follows:

$$\begin{aligned} \text{Now } P(\max(X_1, X_2, \dots, X_n) \leq 1 - \epsilon) \\ &= P(X_1 \leq 1 - \epsilon, X_2 \leq 1 - \epsilon, \dots, X_n \leq 1 - \epsilon) \\ &= (P(X_1 \leq 1 - \epsilon))^n \quad \because X_1, X_2, \dots \text{ are independent} \end{aligned}$$

Now  $X_1$  is  $U[-1, 1]$   $\therefore P(X_1 \leq x) = \frac{x - (-1)}{1 - (-1)}$

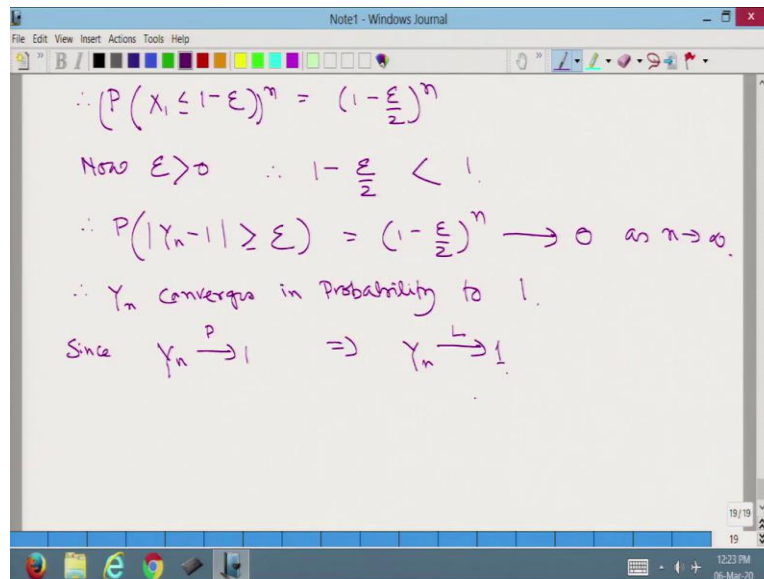

$$\therefore P(X_1 \leq 1 - \epsilon) = \frac{1 - \epsilon + 1}{2} = \frac{1 - \epsilon}{2} = \frac{x + 1}{2}$$

The Windows taskbar at the bottom shows the date as 06-Mar-20 and the time as 12:21 PM.

Now, probability maximum of  $X_1, X_2, X_n$  less than equal to 1 minus epsilon is equal to probability  $X_1$  less than equal to 1 minus epsilon  $X_2$  less than equal to 1 minus epsilon  $X_n$  less than equal to 1 minus epsilon is equal to probability  $X_1$  less than equal to 1 minus epsilon, this whole to the power  $n$ . Since,  $X_1, X_2$  are independent.

Now,  $x_1$  is uniform, in minus 1 to 1, therefore, probability  $x_1$  less than equal to  $x$  is equal to  $x$  minus 1 upon 1 minus 1 is equal to  $x$  plus 1 upon 2. Therefore, probability  $X_1$  less than equal to 1 minus epsilon is equal to 1 minus epsilon plus 1 divided by 2 is equal to 1 minus epsilon by 2.

(Refer Slide Time: 33:45)

The image shows a handwritten derivation in a Windows Journal window. The text is as follows:

$$\therefore P(X_1 \leq 1 - \frac{\epsilon}{2})^n = (1 - \frac{\epsilon}{2})^n$$

Now  $\epsilon > 0 \therefore 1 - \frac{\epsilon}{2} < 1$ .

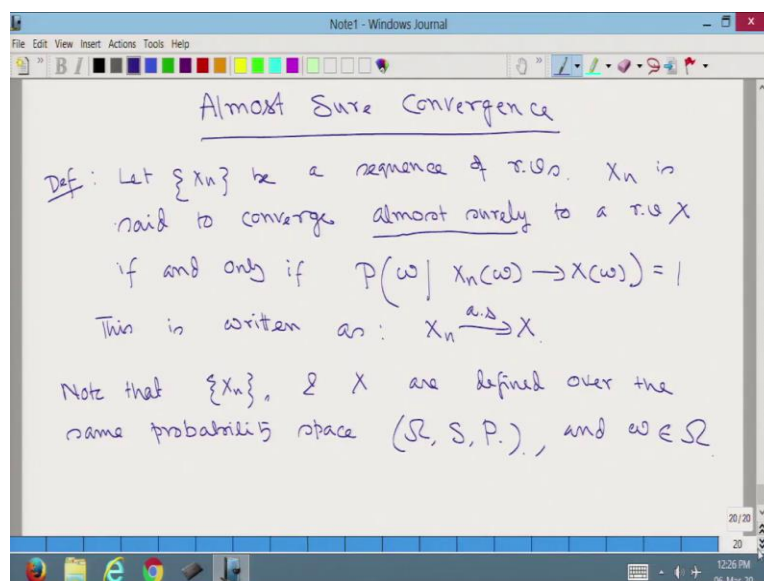

$$\therefore P(|Y_n - 1| \geq \epsilon) = (1 - \frac{\epsilon}{2})^n \rightarrow 0 \text{ as } n \rightarrow \infty.$$

$\therefore Y_n$  converges in Probability to 1.

Since  $Y_n \xrightarrow{P} 1 \Rightarrow Y_n \xrightarrow{L} 1$ .

Therefore, probability  $X_1$  less than equal to 1 minus epsilon whole to the power  $n$  is equal to 1 minus epsilon by 2 whole to the power  $n$ . Now, epsilon is greater than 0, therefore 1 minus epsilon by 2 is strictly less than 1. Therefore, probability modulus of  $Y_n$  minus 1 greater than equal to epsilon, which is equal to 1 minus epsilon by 2 whole to the power  $n$  converges to 0 as  $n$  goes to infinity. Therefore,  $Y_n$  converges in probability to 1 and since  $Y_n$  converges in probability to 1 implies that  $Y_n$  converges in distribution also to the constant one.

(Refer Slide Time: 35:26)

The image shows a handwritten definition of Almost Sure Convergence in a Windows Journal window. The text is as follows:

Almost Sure Convergence

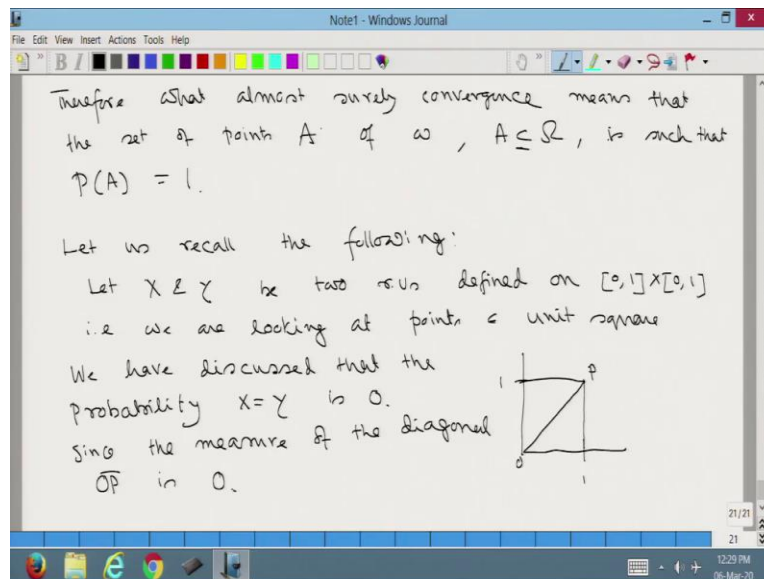

Def: Let  $\{X_n\}$  be a sequence of r.v.s.  $X_n$  is said to converge almost surely to a r.v.  $X$  if and only if  $P(\omega | X_n(\omega) \rightarrow X(\omega)) = 1$

This is written as:  $X_n \xrightarrow{a.s.} X$ .

Note that  $\{X_n\}$ , &  $X$  are defined over the same probability space  $(\Omega, \mathcal{S}, P.)$ , and  $\omega \in \Omega$ .

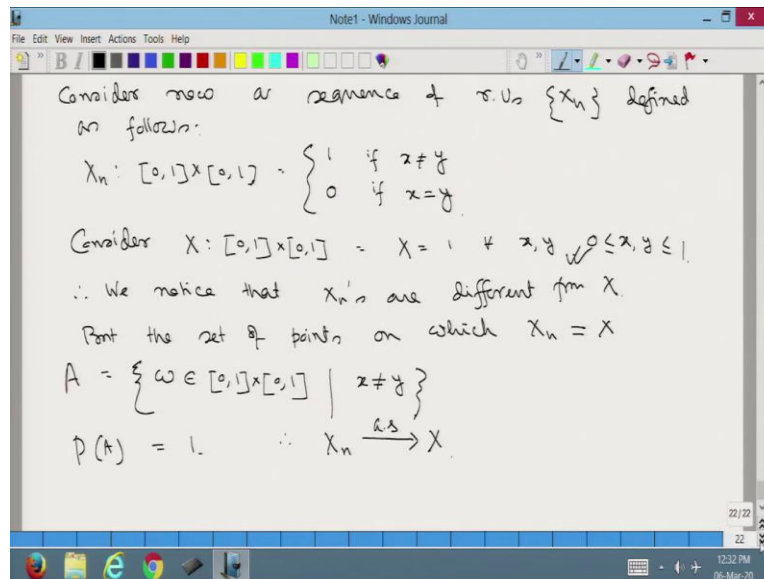

Okay friends, let me now talk about another mode of convergence, which is called almost sure convergence. Definition let  $x_n$  be a sequence of random variables  $X_n$  is said to converge almost surely to a random variable  $x$ , if and only if probability of  $\omega$  such that  $X_n(\omega)$  converges to  $X(\omega)$  is equal to 1 and this is written as  $X_n$  almost surely converging to  $x$ . Note that all  $X_n$  and  $X$  are defined over the same probability space  $\omega$  is  $\Omega$  and small  $\omega$  belongs to capital  $\Omega$ .

(Refer Slide Time: 37:39)

Therefore, what almost surely convergence means that this set of points have  $A$  of small  $\omega$ .  $A$  contained in capital  $\Omega$  is such that probability of  $A$  is equal to 1. So, let us recall the following, let  $x$  and  $y$  be two random variables defined on  $0$  cross  $1$ ,  $0$  to  $1$ , cross  $0$  to  $1$  that is we are looking at points belonging to unit square. We have discussed that the probability  $X$  is equal to  $Y$  is  $0$  because the event  $X$  is equal to  $Y$  means the points are chosen from this diagonal and since the measure of the diagonal  $OP$  say is  $0$ .

(Refer Slide Time: 40:22)

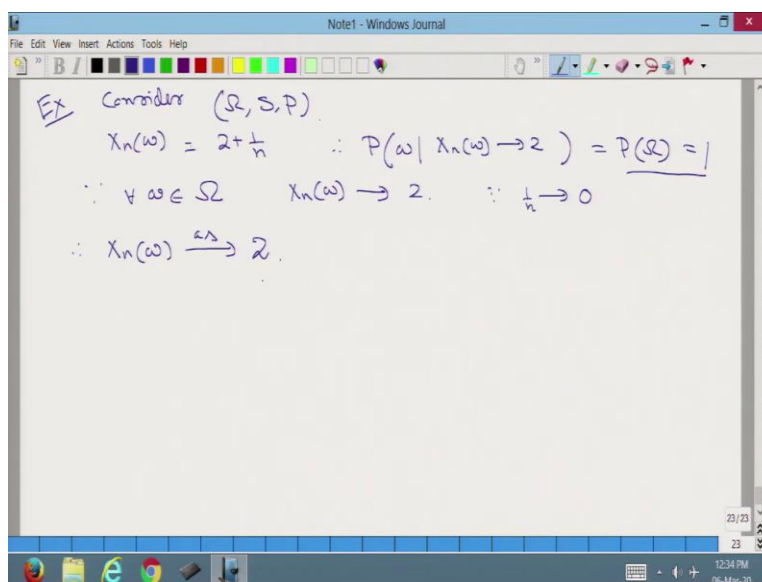

Therefore, consider now a sequence of random variables  $X_n$  defined as follows  $X_n$  is defined from  $[0,1] \times [0,1]$  such that this takes the value 1 if  $x$  is not equal to  $y$  and 0 if  $x$  is equal to  $y$ . Consider  $X$  to be defined on the same  $\Omega$  such that  $X$  is equal to 1 for all  $x, y$  such that  $0 \leq x, y \leq 1$ .

Therefore, we noticed that  $X_n$ 's are different from  $X$ , but this set of points on which  $X_n$  is equal to  $X$  is equal to all  $\omega$  belonging to  $[0,1] \times [0,1]$  such that  $x \neq y$ . So, if we call it  $A$ , then probability of  $A$  is equal to 1. Therefore,  $X_n$  converges almost surely to the random variable  $X$ , which takes value 1 throughout the entire unit square.

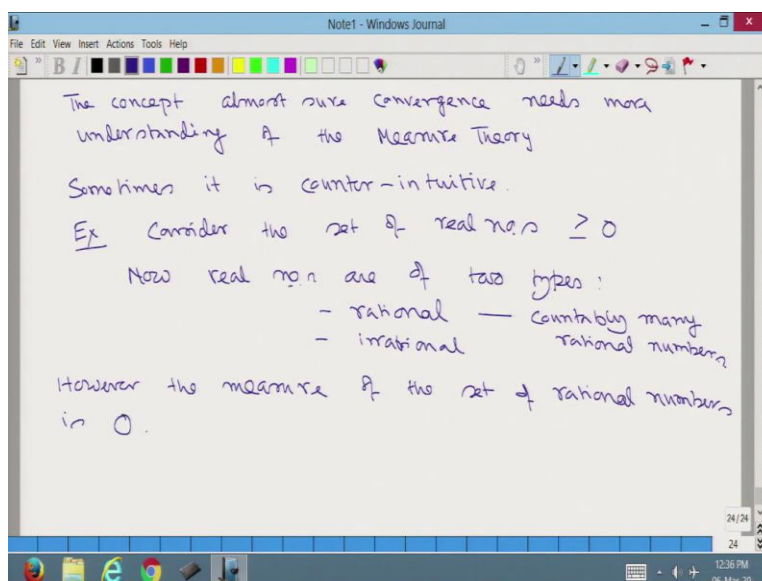

(Refer Slide Time: 42:54)

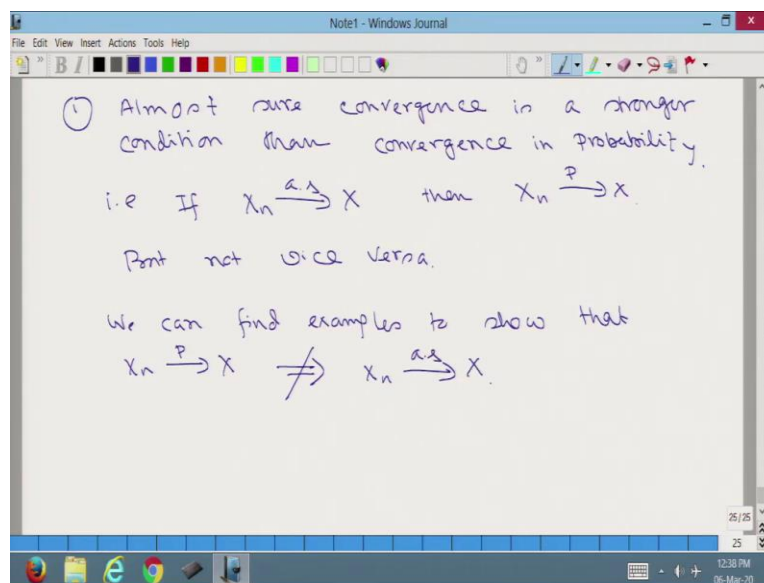

Another example consider some probability space  $\Omega$  SP such that  $X_n \omega$  is equal to 2 plus 1 by n. Therefore, probability of  $\omega$  such that  $X_n \omega$  converges to 2 is equal to probability of  $\omega$  is equal to one. Since, for all  $\omega$  belonging to capital  $\Omega$   $X_n \omega$  converges to 2, since 1 by n converges to 0. Therefore,  $X_n \omega$  almost surely converges to the constant 2.

(Refer Slide Time: 44:04)

Now, the concept of almost sure convergence needs more understanding of the measure theory. Sometimes it is counter intuitive say for example consider the set of real numbers say greater than equal to 0 that is all positive real numbers. Now, real numbers are of two types, rational and irrational. We all know that there are countably many rational numbers. However, the measure of the set of rational numbers is 0, although there are infinitely many rational numbers. To understand this concept, one needs to study deeper level of mathematics is I am not going much into the detail.

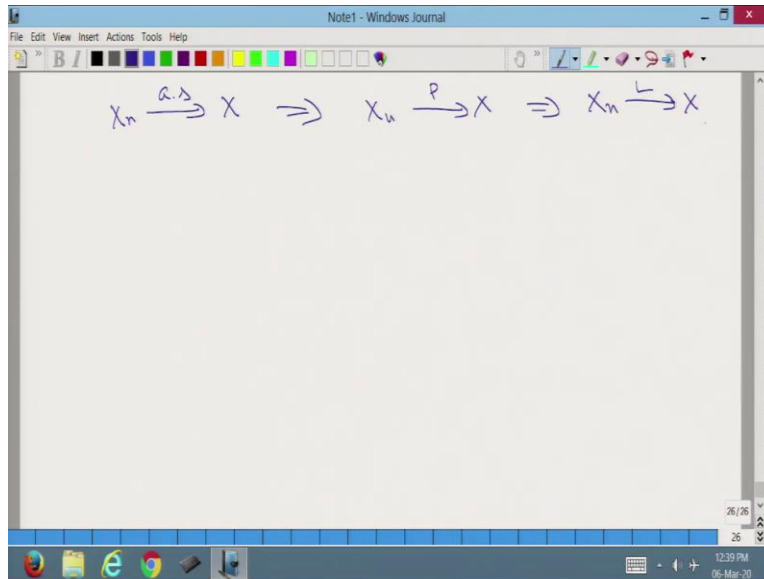

(Refer Slide Time: 46:29)

So, I conclude the talk with the following information that almost sure convergence is a stronger condition than convergence in probability. That is if  $X_n$  converges almost surely to  $x$  then  $X_n$  converges in probability to  $x$ , but not vice versa. We can find examples to show that  $X_n$  converges in probability to  $X$  does not imply  $X_n$  converges almost surely to  $X$ .

I want you to remember this fact, because we shall need almost your convergence for when we study strong law of large numbers in subsequent lectures.

(Refer Slide Time: 48:12)

$$X_n \xrightarrow{a.s.} X \Rightarrow X_n \xrightarrow{P} X \Rightarrow X_n \xrightarrow{L} X$$

Therefore, we conclude that  $X_n$  almost surely converging to  $x$  implies  $X_n$  converging in probability to  $x$ , which implies  $X_n$  converging in distribution to  $x$ . So, with that message, I stop here today from the next class. I shall start with laws of large numbers. Okay then thank you.
